JavaScript Programming

Mendel Rosenblum

How do you program in JavaScript?

From Wikipedia:

> …
>
> ... supporting **object-oriented**, **imperative**, and **functional programming**
>
> ...

- Mostly programming conventions (i.e. patterns) rather than language features
  - ECMAScript adding language features (e.g. `class`, `=>`, etc.)

Object-oriented programming: methods

- A property of an object can be a function

```
var o = {count: 0};
o.increment = function (amount) {
    if (amount == undefined) {
        amount = 1;
    }
    this.count += amount;
    return this.count;
}
```

- Method invocation:

```
o.increment();   // returns 1
o.increment(3);  // returns 4
```

this

- In methods `this` will be bound to the object

```
var o = {oldProp: 'this is an old property'};
o.aMethod = function() {
  this.newProp = "this is a new property";
  return Object.keys(this);  // will contain 'newProp'
}
o.aMethod(); // will return ['oldProp','aMethod','newProp']
```

- In non-method functions:
  - this will be the global object
  - Or if `"use strict";` this will be `undefined`

functions can have properties too
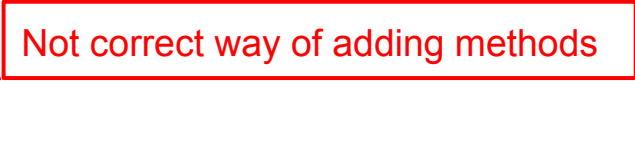

```
function plus1(value) {
    if (plus1.invocations == undefined) {
        plus1.invocations = 0;
    }
    plus1.invocations++;
    return value + 1;
}
```

- `plus1.invocations` will be the number times function is called

- Acts like static/class properties in object-oriented languages

Object-oriented programming: classes

Functions are classes in JavaScript: Name the function after the class

```
function Rectangle(width, height) {
    this.width = width;
    this.height = height;
    this.area = function() { return this.width*this.height; }
}
var r = new Rectangle(26, 14);    // {width: 26, height: 14}
```

Not correct way of adding methods

Functions used in this way are called **constructors**:

```
r.constructor.name == 'Rectangle'
```

console.log(r): Rectangle { width: 26, height: 14, area: [Function] }

Object-oriented programming: inheritance

- Javascript has the notion of a **prototype** object for each object instance
  - Prototype objects can have prototype objects forming a **prototype chain**

- On an object property read access JavaScript will search the up the prototype chain until the property is found
  - Effectively the properties of an object are its **own** property in addition to all the properties up the prototype chain. This is called prototype-based inheritance.

- Property updates are different: always create property in object if not found
  - Can lead to fun in AngularJS

Using prototypes

```
function Rectangle(width, height) {
    this.width = width;
    this.height = height;
}
Rectangle.prototype.area = function() {
    return this.width*this.height;
}
var r = new Rectangle(26, 14);   // {width: 26, height: 14}
var v = r.area();        // v == 26*14
Object.keys(r) == [ 'width', 'height' ] // own properties
```

Note: Dynamic - changing prototype will cause all instances to change

Prototype versus object instances

```
var r = new Rectangle(26, 14);
```

Understand the difference between:

```
    r.newMethod = function() { console.log('New Method called'); }
```

And:

```
    Rectangle.prototype.newMethod =
            function() { console.log('New Method called'); }
```

Inheritance

```
Rectangle.prototype = new Shape(...);
```

- If desired property not in `Rectangle.prototype` then JavaScript will look in `Shape.prototype` and so on.
  - Can view prototype objects as forming a **chain**. Lookups go up the prototype chain.

- Prototype-based inheritance
  - Single inheritance support
  - Can be dynamically created and modified

ECMAScript version 6 extensions

```
class Rectangle extends Shape {  // Definition and Inheritance
  constructor(height, width) {
    this.height = height;
    this.width = width;
  }

  area() {                       // Method definition
    return this.width * this.height;
  }

  static countRects() {       // Static method
    ...
  }

}

var r = new Rectangle(10,20);
```

Functional Programming

- Imperative:

```
for (var i = 0; i < anArr.length; i++) {
    newArr[i] = anArr[i]*i;
}
```

- Functional:

```
newArr = anArr.map(function (val, ind) {
    return val*ind;
});
```

- Can write entire program as functions with no side-effects

```
anArr.filter(filterFunc).map(mapFunc).reduce(reduceFunc);
```

Functional Programming

- Imperative:
  ```
  for (var i = 0; i < anArr.length; i++) {
    newArr[i] = anArr[i]*i;
  }
  ```
- Functional:
  ```
  newArr = anArr.map((val, ind) => val*ind);  // Arrow function
  ```

- Can write entire program as functions with no side-effects
  ```
  anArr.filter(filterFunc).map(mapFunc).reduce(reduceFunc);
  ```

Can mostly but not totally avoid functional style

- Asynchronous events done with callback functions

  Browser:
  ```
  function callbackFunc() { console.log("timeout"); }
   setTimeout(callbackFunc, 3*1000);
  ```

  Server:
  ```
  function callbackFunc(err, data) { console.log(String(data)); }
  fs.readFile('/etc/passwd', callbackFunc);
  ```

- Node.js programming: Write function for HTTP request processing

Closures

An advanced programing language concept you need to know about

```
    var globalVar = 1;
    function localFunc(argVar) {
      var localVar = 0;
      function embedFunc() {return ++localVar + argVar + globalVar;}
      return embedFunc;
    }
var myFunc = localFunc(10);   // What happens if a call myFunc()? Again?
```

- myFunc **closure** contains `argVar, localVar` and `globalVar`

Using Scopes and Closures

- Consider effect on the scopes of:

```
var i = 1;
. . .
```

Versus

```
(function () {
    var i = 1;
    . . .
})();
```

Using closures for private object properties

```
var myObj = (function() {
    var privateProp1 = 1;   var privateProp2 = "test";
    var setPrivate1 = function(val1)  { privateProp1 = val1; }
    var compute = function() {return privateProp1 + privateProp2;}
    return {compute: compute, setPrivate1: setPrivate1};
})();

typeof myObj;          // 'object'
Object.keys(myObj);  //  [ 'compute', 'setPrivate1' ]
```

What does myObj.compute() return?

Closures can be tricky with imperative code

```
//  Read files './file0' and './file1' and return their length
for (var fileNo = 0; fileNo < 2; fileNo++) {
    fs.readFile('./file' + fileNo, function (err, data) {
        if (!err) {
            console.log('file', fileNo, 'has length', data.length);
        }
    });
}
```

- Ends up printing two files to console both starting with:
  ```
  file 2 has length
  ```
 Why?

Stepping through the execution

```
for (var fileNo = 0; fileNo < 2; fileNo++) {
    fs.readFile('./file' + fileNo, function (err, data) {
        if (!err) {
            console.log('file', fileNo, 'has length', data.length);
        }
    });
}
```

Execution starts here: fileNo= 0

Stepping through the execution

```javascript
for (var fileNo = 0; fileNo < 2; fileNo++) {
    fs.readFile('./file' + fileNo, function (err, data) {
        if (!err) {
            console.log('file', fileNo, 'has length', data.length);
        }
    });
}
```

Call the function `fs.readFile`, before we can we must evaluate the arguments: the first argument results from the string concatenation operation forming `"./file0"`, the second argument is a function which is passed as a function and its closure containing the variables accessed by the function. In this case only `fileNo` is accessed by the function so the closure contains `fileNo` (which is currently 0).

Stepping through the execution

```
for (var fileNo = 0; fileNo < 2; fileNo++) {
    fs.readFile('./file' + fileNo, function (err, data) {
        if (!err) {
            console.log('file', fileNo, 'has length', data.length);
        }
    });
}
```

Note that `fs.readFile` returns after it has started reading the file but before it has called the callback function. The execution does the `fileNo++` and calls back to `fs.readFile` with an argument of `"./file1"` and a new closure and function. The closure has only `fileNo` (which is currently 1).

Stepping through the closure example

```
for (var fileNo = 0; fileNo < 2; fileNo++) {
    fs.readFile('./file' + fileNo, function (err, data) {
        if (!err) {
            console.log('file', fileNo, 'has length', data.length);
        }
    });
}
```

After creating two function with closures and calling fs.readFile twice the `for` loop finishes. Some time later in the execution the file reads will finish and `fs.readFile` will call the functions we passed. Recall that `fileNo` is now 2.

Sometime later: `file0` read finishes...

```
for (var fileNo = 0; fileNo < 2; fileNo++) {
    fs.readFile('./file' + fileNo, function (err, data) {
        if (!err) {
            console.log('file', fileNo, 'has length', data.length);
        }
    });
}
```

'./file0' is read so our callback starts executing err
is falsy so we go to the console.log statement.

Running callbacks....

```javascript
for (var fileNo = 0; fileNo < 2; fileNo++) {
    fs.readFile('./file' + fileNo, function (err, data) {
        if (!err) {
            console.log('file', fileNo, 'has length', data.length);
        }
    });
}
```

When evaluating the arguments to `console.log` we go to the closure and look at the current value of `fileNo`. We find it as 2. The result is we print the correct `data.length` but the wrong file number. The same thing happens for the `'./fileNo1'` callback.

Broken fix #1 - Add a local variable

```
for (var fileNo = 0; fileNo < 2; fileNo++) {
    var localFileNo = fileNo;
    fs.readFile('./file' + localFileNo, function (err, data) {
        if (!err) {
            console.log('file', localFileNo,'has length',data.length);
        }
    });
}
```

Closure for callback now contains `localFileNo`. Unfortunately when the callback functions run `localFileNo` will be **1**. Better than before since one of the printed lines has the correct fileNo. □

A fix - Make fileNo an argument

```
function printFileLength(fileNo) {
    fs.readFile('./file' + fileNo, function (err, data) {
        if (!err) {
            console.log('file', fileNo, 'has length', data.length);
        }
    });
}
for (var fileNo = 0; fileNo < 2; fileNo++) {
    printFileLength(fileNo);
}
```

Note: This works but sometimes it prints the `file0` line first and sometimes it prints the `file1` line first.

JavaScript Object Notation (JSON)

```
var obj = { ps: 'str', pn: 1, pa: [1,'two',3,4], po: { sop: 1}};

var s = JSON.stringify(obj) =
    '{"ps":"str","pn":1,"pa":[1,"two",3,4],"po":{"sop":1}}'
```

typeof s == 'string'
JSON.parse(s) // returns object with same properties

- JSON is the standard format for sending data to and from a browser

JavaScript: The Bad Parts

Declaring variables on use - Workaround: Force declarations

```
var myVar = 2*typeoVar + 1;
```

Automatic semicolon insertion - Workaround: Enforce semicolons with checkers

```
return
    "This is a long string so I put it on its own line";
```

Type coercing equals: == - Workaround: Always use ===,!== instead

```
("" == "0") is false but (0 == "") is true, so is (0 == '0')
(false == '0') is true as is (null == undefined)
```

`with, eval` - Workaround: Don't use

Some JavaScript idioms

- Assign a default value

  ```
  hostname = hostname || "localhost";
  port = port || 80;
  ```

- Access a possibly undefined object property

  ```
  var prop = obj && obj.propname;
  ```

- Handling multiple `this`:

  ```
  fs.readFile(this.fileName + fileNo, function (err, data) {
      console.log(this.fileName, fileNo);  // Wrong!
  });
  ```

Some JavaScript idioms

- Assign a default value

```
hostname = hostname || "localhost";
port = port || 80;
```

- Access a possible undefined object property

```
var prop = obj && obj.propname;
```

- Handling multiple `this`: `self`

```
var self = this;
fs.readFile(self.fileName + fileNo, function (err, data) {
    console.log(self.fileName,fileNo);
});
```
